2.4 Segment tree range update range query

2.4.1 Arithmetic progression sum update, query sum

Description: Makes arithmetic progression updates in range and sum queries.
Usage: Considering $PA(A, R) = [A + R, A + 2R, A + 3R, ...]$

- **update_set(l, r, A, R):** sets [l, r] to PA(A, R)
- **update_add(l, r, A, R):** sum PA(A, R) in [l, r]
- **query(l, r):** sum in range [l, r]

Time: build $O(N)$, updates and queries $O(logN)$

2.9 Lichao Tree (dynamic)

Description: Lichao Tree that creates the nodes dynamically, allowing to query and update from range $[MAXL, MAXR]$
Usage:

- $query(x)$: find the highest point among all lines in the structure
- $add(a, b)$: add a line of form $y = ax + b$ in the structure
- $addSegment(a, b, l, r)$: add a line segment of form $y = ax + b$ which covers from range $[l, r]$

Time: $O(\log N)$

```

2.10 Merge sort tree

Description: Like a segment tree but each node stores the ordered subsegment it represents.
Usage:

- $inrange(l, r, a, b)$: counts the number of positions i, $l \le i \le r$ such that $a \le x_i \le b$.

Time: Build $O(N \log N^2)$, inrange $O(\log N^2)$
Memory: $O(n \log N)$

```
template <class T>
struct MergeSortTree {
  int n;
  vector<vector<T>> st;
  MergeSortTree(vector<T> &xs)
      : n(len(xs)), st(n << 1) {

      if (r & 1) ans += count(--r, a, b);
    }
    return ans;
  }
};
```

2.11 Mex with update

Description: This DS allows you to mantain an array of elments, insert, and remove, and query the MEX at any time.
Usage:

- $Mex(mxsz)$: Initialize the DS, $mxsz$ must be the maximum number of elements that the structure may have.
- $add(x)$: just adds one copy of x.
- $rmv(x)$: just remove a copy of x.
- $operator()$: returns the MEX.

Time:

- $Mex(mxsz)$: $O(\log mxsz)$
- $add(x)$: $O(\log mxsz)$
- $rmv(x)$: $O(\log mxsz)$
- $operator()$: $O(1)$

```
struct Mex {
  int mx_sz;
  vi hs;
  set<int> st;
  Mex(int _mx_sz) : mx_sz(_mx_sz), hs(mx_sz + 1) {
    auto it = st.begin();
    rep(i, 0, mx_sz + 1) it = st.insert(it, i);
  }
  void add(int x) {
    if (x > mx_sz) return;
    if (!hs[x]++) st.erase(x);
  }
  void rmv(int x) {
    if (x > mx_sz) return;
    if (!--hs[x]) st.emplace(x);
  }

    for (auto xi : xs) add(xi);
  }
};
```

2.12 Orderd Set (GNU PBDS)

Usage: If you need an ordered **multi** set you may add an id to each value. Using greater_equal, or less_equal is considered undefined behavior.

- **order_of_key (k)**: Number of items strictly smaller/greater than k .
- **find_by_order(k)**: K-th element in a set (counting from zero).

Time: Both $O(\log N)$
Warning: Is 2 or 3 times slower then a regular set/map.

```
#include <ext/pb_ds/assoc_container.hpp>
#include <ext/pb_ds/tree_policy.hpp>
using namespace __gnu_pbds;
template <typename T>
using ordered_set =
    tree<T, null_type, less<T>, rb_tree_tag,
         tree_order_statistics_node_update>;
```

2.13 Prefix Sum 2D

Description: Given an 2D array with N lines and M columns, find the sum of the subarray that have the left upper corner at $(x1, y1)$ and right bottom corner at $(x2, y2)$.
Time: Build $O(N \cdot M)$, Query $O(1)$.

```
template <typename T>
struct psum2d {
  vector<vector<T>> s;
  vector<vector<T>> psum;
  psum2d(vector<vector<T>> &grid, int n, int m)

      }
  }

  }
};
```

2.16 Venice Set

Description: A container that you can insert q copies of element e, increment every element in the contaiver in x, query which is the best element and it's quantity and also remove k copies of the greatest element.
Time:
- add elment $O(\log N)$
- remove $O(\log N)$
- update: $O(1)$
- query $O(1)$

```
template <typename T = ll>
struct VeniceSet {
  using T2 = pair<T, ll>;
  priority_queue<T2, vector<T2>, greater<T2>> pq;
  T acc;
  VeniceSet() : acc() {}

    pq.pop();
    q -= k;
    if (q) pq.emplace(e, q);
  }
};
```

2.17 Venice Set (complete)

Description: A container which you can insert elements update all at once and also make a few queries
Usage:
- $add\_element(e, q)$: adds q copies of e, if no q is provided adds a single one
- $update\_all(x)$: increment every value by x
- $erase(e)$: removes every copy of e, and returns how much was removed.
- $count(e)$: returns the number of e in the container
- $high()/low()$: returns the hightest/lowest element, and it's quantity
- $pop\_low(q)/pop\_high(q)$: removes q copies of the lowest/highest elements if no q is provided removes all copies of the lowest/highest element.

You may answer which is the $K - th$ value and it's quantity using an $ordered\_set$.
Probably works with other operations
Time: Considering N the number of distinct numbers in the container
- $add\_element(e, q)$: $O(\log(N))$
- $update\_all(x)$:$O(1)$
- $erase(e)$: $O(\log(N))$
- $count(e)$: $O(\log(N))$
- $high()/low()$: $O(1)$
- $pop\_low(q)/pop\_high(q)$: worst case is $O(N \cdot \log(N))$ if you remove all elements and so on...

Warning: There is no error handling if you try to *pop* more elements than exists or related stuff

```

3 Dynamic Programming

3.1 Binary Knapsack (bottom up)

Description: Given the points each element have, and it repespective cost, computes the maximum points we can get if we can ignore/choose an element, in such way that the sum of costs don't exceed the maximum cost allowed.
Time: $O(N * W)$
Warning: The vectors VS and WS starts at one, so it need an empty value at index 0.

3.7 Sum of Subsets

Description: Allows you to find if some mask X is a super mask of any of the given masks
Usage: Call *build* with the *masks* then it returns a vector of bool V where V_X says if X is a super mask of any of the initial maks
You can change it to count how many submasks of each mask exsists, by changing the bitwise or by a plus sign...
Time: $O(LOG \cdot 2^{LOG})$

6.2 2-SAT

Description: Calculates a valid assignment to boolean variables a, b, c,... to a 2-SAT problem, so that an expression of the type $(a||b)\&\&(!a||c)\&\&(d||!b)\&\&...$ becomes true, or reports that it is unsatisfiable.
Usage: Negated variables are represented by bit-inversions ($\sim x$).
Returns true iff it is solvable ts.values[0..N-1] holds the assigned values to the vars.
Time: $O(N + E)$, where N is the number of boolean variables, and E is the number of clauses.

9.2 catalan

Description: Recursive formula: $C_0 = C_1 = 1$
$C_n = \sum_{k=0}^{n-1} C_k C_{n-1-k}, n \geq 2$
Analytical formula: $C_n = \binom{2n}{n} - \binom{2n}{n-1} = \frac{1}{n+1}\binom{2n}{n}, n \geq 0$
The first few numbers Catalan numbers, C_n (starting from zero):
$1, 1, 2, 5, 14, 42, 132, 429, 1430, \ldots$
The Catalan number C_n is the solution for:

- Number of correct bracket sequence consisting of n opening and n closing brackets.
- The number of rooted full binary trees with $n + 1$ leaves (vertices are not numbered). A rooted binary tree is full if every vertex has either two children or no children.
- The number of ways to completely parenthesize $n + 1$ factors.
- The number of triangulations of a convex polygon with $n + 2$ sides (i.e. the number of partitions of polygon into disjoint triangles by using the diagonals).
- The number of ways to connect the $2n$ points on a circle to form n disjoint chords.
- The number of non-isomorphic full binary trees with n internal nodes (i.e. nodes having at least one son).
- The number of monotonic lattice paths from point $(0, 0)$ to point (n, n) in a square lattice of size $n \times n$, which do not pass above the main diagonal (i.e. connecting $(0, 0)$ to (n, n)).
- Number of permutations of length n that can be stack sorted (i.e. it can be shown that the rearrangement is stack sorted if and only if there is no such index $i < j < k$, such that $a_k < a_i < a_j$).
- The number of non-crossing partitions of a set of n elements.
- The number of ways to cover the ladder $1 \ldots n$ using n rectangles (The ladder consists of n columns, where i^{th} column has a height i).
